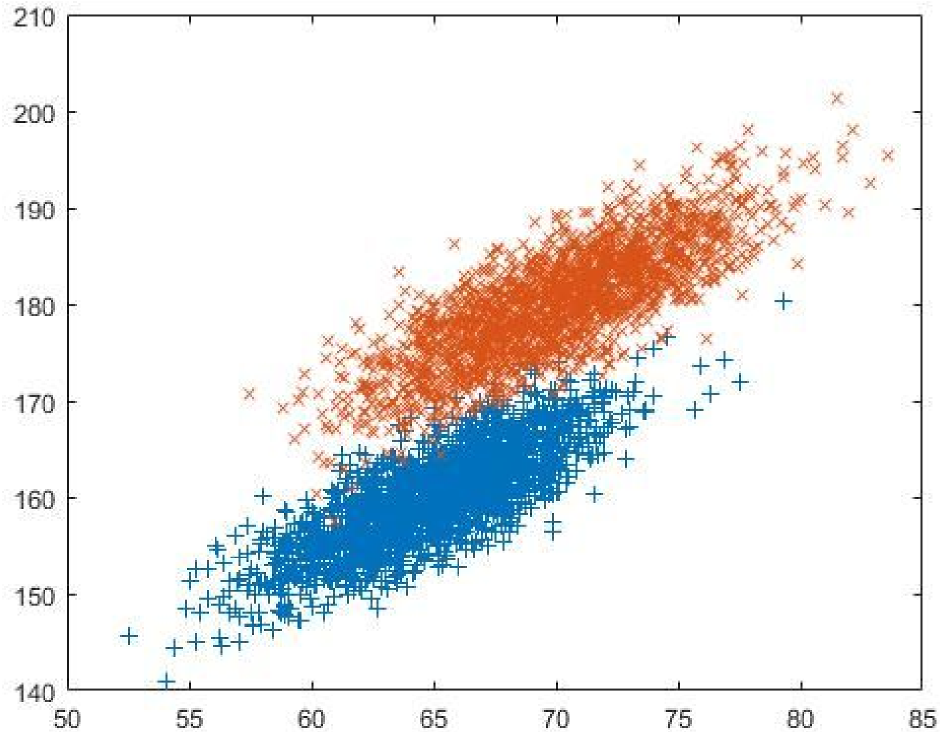
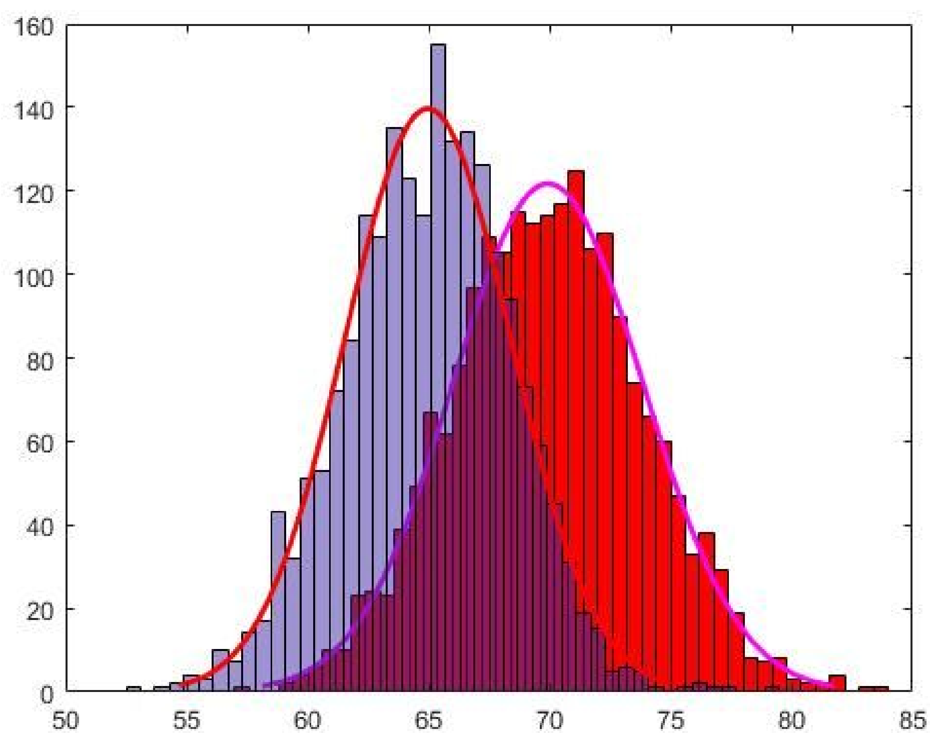
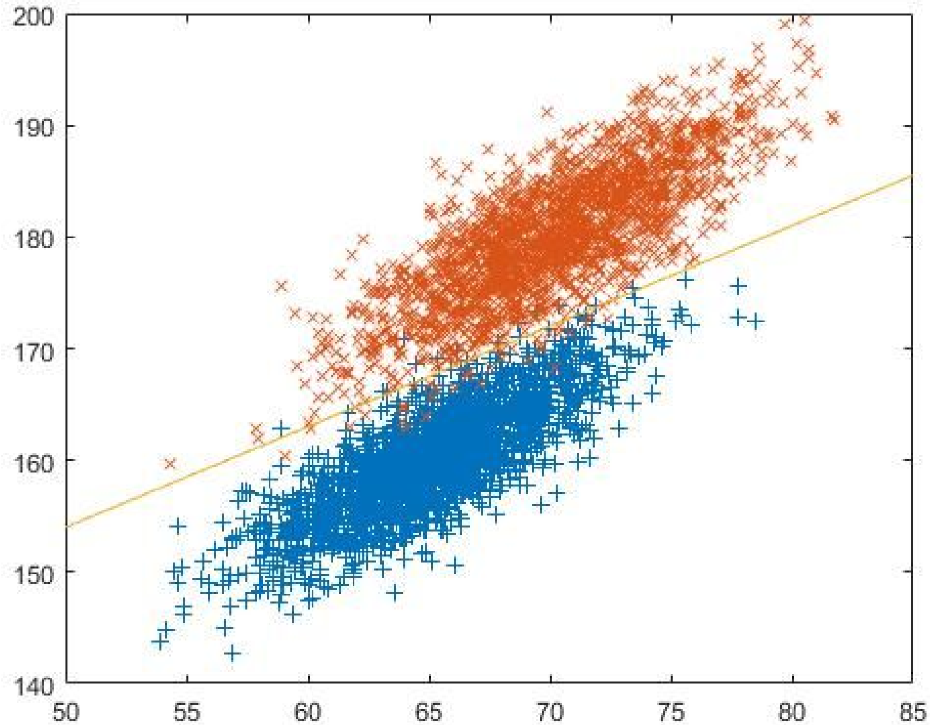
To generate a random sample of normally distributed data we created a covariance matrix and correlation matrix. This allowed us to generate a multivariable normally distributed sample of 2000 men and 2000 women around a set mean for height and weight with predetermined standard deviations. Because we used a covariance matrix we can break out any axis of data such as height and analyse it individually. We used a random function that was reproducible for the sake of presentation. From this sample we manually created a distinguishing line and calculated the accuracy, error, true positive rate, true negative rate, false positive rate, and false negative rate. It is interesting how adding a second variable substantially increased the accuracy, from .7403 to .9480.

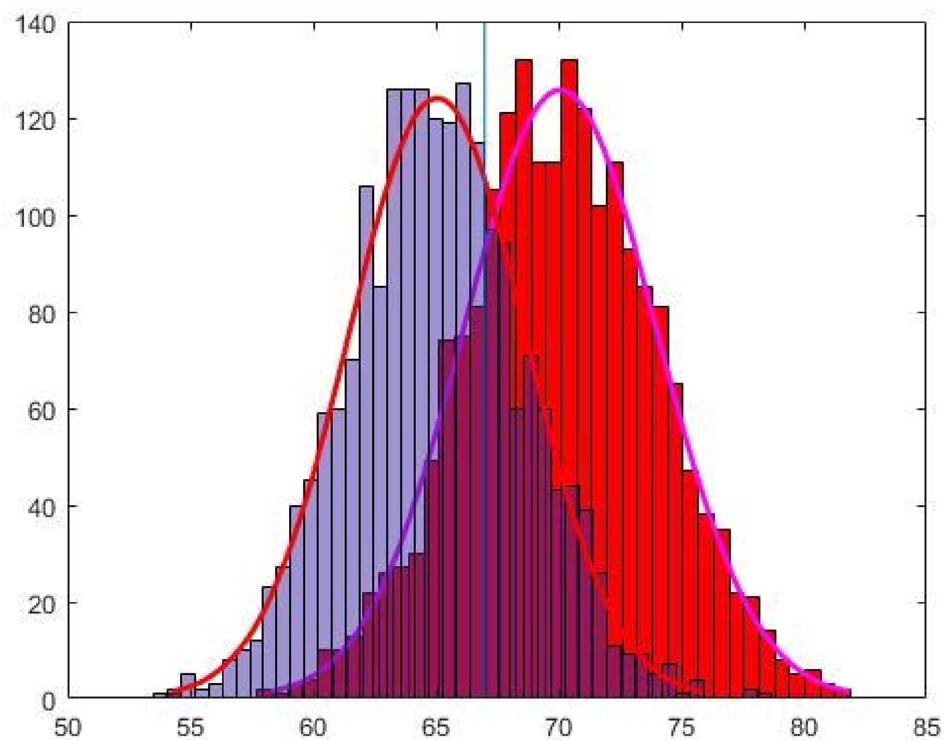
Data Without Separation Lines:





Data with Separation Lines:





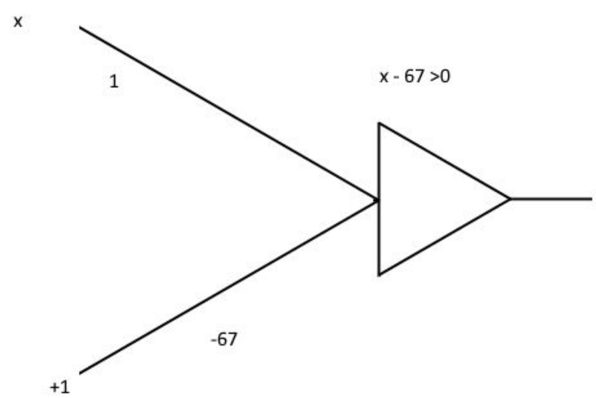
Contrast Artificial Neuron:

For our sample the equations are $x = 67$ while distinguishing based solely on height, and $y = 0.9x + 104$ when distinguishing by both height and weight

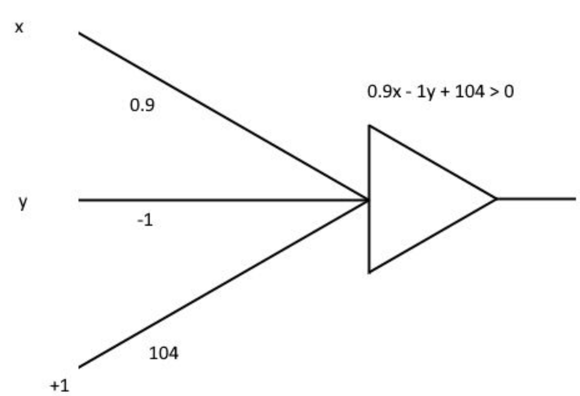
Equation Scenario A: $1x - 67 > 0$
Equation Scenario B: $0.9x - 1y + 104 > 0$

Weights of Scenario A: [1 -67]
Weights of Scenario B: [1.3 1 -257]

Height Artificial Neuron:



Height and Weight Artificial Neuron:



Scenario A:

Error:	0.2597
Accuracy:	0.7403
True Positive Rate:	0.7720
True Negative Rate:	0.7085
False Positive Rate:	0.2915
False Negative Rate:	0.2280

Scenario B:

Error:	0.0520
Accuracy:	0.9480
True Positive Rate:	0.9030
True Negative Rate:	0.9930
False Positive Rate:	0.0070
False Negative Rate:	0.0970

CODE:
